14-stage binary ripple counter with oscillator

74HC/HCT4060

FEATURES

- · All active components on chip
- · RC or crystal oscillator configuration
- Output capability: standard (except for R_{TC} and C_{TC})
- I_{CC} category: MSI

GENERAL DESCRIPTION

The 74HC/HCT4060 are high-speed Si-gate CMOS devices and are pin compatible with "4060" of the "4000B" series. They are specified in compliance with JEDEC standard no. 7A.

The 74HC/HCT4060 are 14-stage ripple-carry counter/dividers and oscillators with three oscillator

terminals (RS, R_{TC} and C_{TC}), ten buffered outputs (Q_3 to Q_9 and Q_{11} to Q_{13}) and an overriding asynchronous master reset (MR).

The oscillator configuration allows design of either RC or crystal oscillator circuits. The oscillator may be replaced by an external clock signal at input RS. In this case keep the other oscillator pins (R_{TC} and C_{TC}) floating.

The counter advances on the negative-going transition of RS. A HIGH level on MR resets the counter (Q_3 to Q_9 and Q_{11} to Q_{13} = LOW), independent of other input conditions.

In the HCT version, the MR input is TTL compatible, but the RS input has CMOS input switching levels and can be driven by a TTL output by using a pull-up resistor to V_{CC} .

QUICK REFERENCE DATA

GND = 0 V; $T_{amb} = 25 \, ^{\circ}C$; $t_r = t_f = 6 \, \text{ns}$

| SYMBOL | PARAMETER | CONDITIONS | TYP | ICAL | UNIT |
|-------------------------------------|---|---|-----|------|------|
| STIVIBUL | PARAMETER | CONDITIONS | НС | нст | UNII |
| t _{PHL} / t _{PLH} | propagation delay | C _L = 15 pF; V _{CC} = 5 V | | | |
| | RS to Q ₃ | | 31 | 31 | ns |
| | Q _n to Q _{n+1} | | 6 | 6 | ns |

| Cı | input capacitance | | 3.5 | 3.5 | pF |
| C _{PD} | power dissipation capacitance per package | notes 1, 2 and 3 | 40 | 40 | pF |

Notes

1. C_{PD} is used to determine the dynamic power dissipation (P_D in μW):

$$P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o)$$
 where:

 f_i = input frequency in MHz

f_o = output frequency in MHz

 $\sum (C_L \times V_{CC}^2 \times f_o) = \text{sum of outputs}$

C_L = output load capacitance in pF

V_{CC} = supply voltage in V

- 2. For HC the condition is $V_I = GND$ to V_{CC} For HCT the condition is $V_I = GND$ to $V_{CC} - 1.5$ V
- 3. For formula on dynamic power dissipation see next pages.

1. The value of additional quiescent supply current (ΔI_{CC}) for a unit load of 1 is given here. To determine ΔI_{CC} per input, multiply this value by the unit load coefficient shown in the table below.

2. Only input MR (pin 12) has TTL input switching levels for the HCT versions.

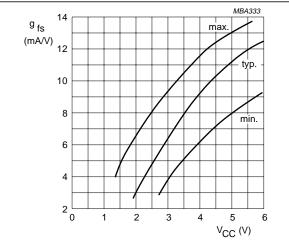

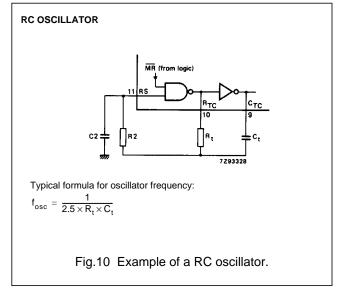

Fig.8 Typical forward transconductance g_{fs} as a function of the supply voltage V_{CC} at $T_{amb} = 25 \, ^{\circ}C$.

TIMING COMPONENT LIMITATIONS

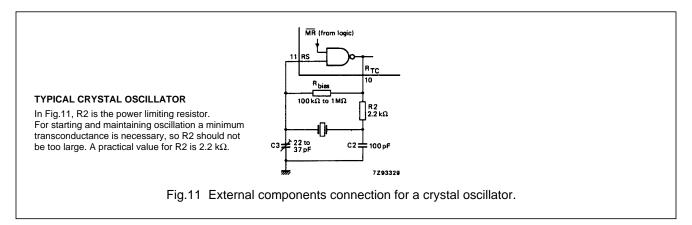

The oscillator frequency is mainly determined by R_tC_t , provided $R2 \approx 2R_t$ and $R2C2 << R_tC_t$. The function of R2 is to minimize the influence of the forward voltage across the input protection diodes on the frequency. The stray capacitance C2 should be kept as small as possible. In consideration of accuracy, C_t must be larger than the inherent stray capacitance. R_t must be larger than the "ON" resistance in series with it, which typically is $280~\Omega$ at $V_{CC} = 2.0~V$, $130~\Omega$ at $V_{CC} = 4.5~V$ and $100~\Omega$ at $V_{CC} = 6.0~V$.

The recommended values for these components to maintain agreement with the typical oscillation formula are: $C_t > 50$ pF, up to any practical value, $10 \text{ k}\Omega < R_t < 1 \text{ M}\Omega$.

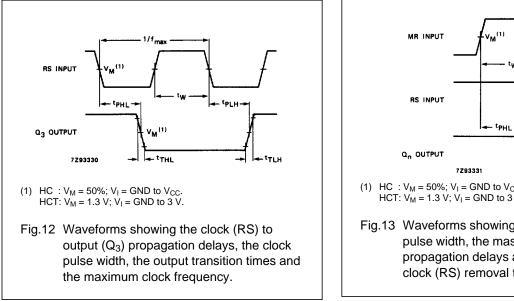

In order to avoid start-up problems, $R_t \ge 1 \text{ k}\Omega$.
